Dosimetry; Radio-chromic solution; Nitro blue tetrazolium; Sodium formate; Absorbance

Abstract
Nitro blue tetrazolium (NBT) solution dosimeters were prepared and investigated based on radiation-induced reduction of NBT\textsuperscript{2+}. NBT solution dosimeters containing different concentrations of NBT dye from 1 to 5 mM were prepared in a solution of ethanol. The dosimeters were irradiated with 6 MV X-ray beam at doses up to 30 Gy. The dose sensitivity of NBT solution increases strongly with increase of concentrations of NBT dye. The dose response of NBT dosimeters increases remarkably by addition of various concentrations of sodium formate (0.5, 2.5 and 5 mM). It becomes more remarkable with increasing pH value of NBT-sodium formate dosimeters. The sensitivity of the solution increased fairly with increase of irradiation temperature, therefore, the response of the solutions has to be corrected under actual processing conditions. The stability of solution dosimeters after irradiation was very high up to 30 days.

Introduction
Treatment of cancer by radiotherapy has increased and developed greatly, therefore quality control of dosimetric techniques in medical applications are needed for providing accurate evaluation of doses absorbed in tumor volume and adjacent tissues. Radio-chromic dosimeters (material that turns color due to a radiation-induced chemical changes) have a long history in the field of ionizing radiation dosimetry [16]. Fricke–gelatin–xenol orange mixture is known as the FGX gel dosimeter can be measured spectrophotometrically [9,10]. FGX gel dosimeter demonstrated...
reproducible linear dose response up to 25 Gy for radiotherapy treatment planning \[6\]. It was found that the most important factors that affect the response of FGX gel dosimeter are diffusion of ferric ions which result in an increase in the concentration of the XO–Fe\(^{3+}\) complex and therefore a change in the optical absorbance of the FGX gel dosimeter.

A dosimeter similar to the present solution based on tetrazolium salt dyes for high dose application such as sterilization and food irradiation was developed \[11\]. Tetrazolium salts have long been known as quaternary ammonium compounds with a significant property of forming water insoluble, highly colored formazans by reduction \[3\]. The reduction/oxidation reactions in tetrazolium salts and the change in their colors by forming formazans can also take place using ionizing radiation \[4,13\]. A considerable increase in dose response of NBT-PVA film dosimeters \[14\] and NBT gel dosimeters \[1\] was observed by adding appropriate concentration of sodium format and Triton X-100. Different concentrations of 2,3,5-triphenyltetrazolium chloride (TTC) in aqueous solution were investigated \[12\]. It was found that a linear response of absorbance increase with dose over the dose range 1–16 kGy. On the other hand, nitro blue tetrazolium (NBT) solution dosimeters were investigated \[11\]. It was found that NBT dosimeters could be used over the dose range of 100–1000 Gy. Recently, aqueous and aqueous-alcoholic solutions containing different concentrations of tetrazolium violet (TV) was measured in the dose range of 250 Gy up to 75 kGy \[7\]. Appleby \[1\] introduced a three dimensional imaging of the high dose (700 Gy) distributions of the radiated tetrazolium (NBT) gel dosimeters via optical scanning techniques. In fact, so far the use of tetrazolium solution dosimeters for low doses has not been reported. Therefore, the present work introduces nitro blue tetrazolium (NBT) solution as single point radio-chromic solution dosimeters that have a potential use in medical dosimetry for radiotherapy treatment planning over the dose range of 2.5–30 Gy.

**Experimental**

The nitro blue tetrazolium chloride, NBTCI\(_2\) (C\(_{40}\)H\(_{30}\)Cl\(_2\)N\(_8\)O\(_{10}\)H\(_2\)O.C\(_4\)H\(_2\)O; MW 867.70) was used as received from Biosynth, USA. Sodium formate (CHN\(_2\)O\(_2\); M W: 68) was used as received from (EMD Chemicals, USA), and 96% ethanol from Merck was used as received as a solvent for the previous chemicals. The solutions were kept in 3 ml sealed glass ampoules and stored in the dark at room temperature (23 ± 1). The pH of the solutions was set with HCl and NaOH, respectively.

Five hours before irradiation, all solution dosimeters were transferred to the temperature controlled radiation source room to reach equilibrium conditions. The irradiation was carried out using the 18 MV X-ray beam (Varian Medical Systems Inc.) with the maximum dose rate of 300 cGy min\(^{-1}\). Each dosimeter ampoule was placed in a polystyrene holder in a water-phantom acrylic tank. The samples were irradiated with different doses at 15 cm depth, 100 cm (SSD) set-up and 10 × 10 cm\(^2\) field size. The samples were transferred back to the refrigerator and kept for about 24 h before optical measurement.

UV/VIS spectrophotometer is used to measure the absorbance of spectra of radiation in the near infrared (700–1100 nm), visible (350–700 nm) and ultra violet (190–350) nm regions. The absorption spectra of irradiated NBT solutions in the wavelength range from 350 to 650 nm were measured using UV/VIS spectrophotometer, model Lambda 850, from Perkin-Elmer, USA. Three samples at each absorbed dose were measured and the average is reported. In general, evaluation of NBT solution dosimeters followed ASTM standard guide for performance characterization of dosimeters and dosimetry systems for use in radiation processing, ASTM E2701-09 (ASTM Standard Guide E2701-09).

**Results and discussion**

**Effect of dye concentration**

Variable concentrations of NBT (pH = 5.6) dye ranging from 1 to 5 mM were used to investigate the effect of the dye concentrations on the response of the NBT dosimeters. The absorption spectra of un-irradiated as well as irradiated NBT solutions were recorded in the range of 450–650 nm. Figure 1 demonstrates the absorbance of 5 mM of NBT (pH = 5.6) in the dose range of 0–30 Gy. The absorption maximum is located at about 521 nm with a shoulder at about 572 nm due to the absorbance of the mono-formazan that forms with an initial G-value of 3 molecule/100 eV \[11\]. It was observed that the absorbance on the long wavelength side of the spectrum gets stronger with the increasing absorbed dose, as a result of formation of di-formazan species from reduction of mono-formazan species.

The dose response curves were established in terms of change in absorbance measured at the absorption peak, 521 nm, \(\Delta A (\Delta A = A_d - A_0)\) versus the absorbed dose, where \(A_d\) and \(A_0\) are absorbance values at 521 nm for irradiated and unirradiated solutions. The dose response curves of the NBT solutions are shown in Fig. 2.

![Figure 1](image-url) Absorbance of 5 mM of NBT solution dosimeters as a function of wavelength for various absorbed doses.
with variable concentrations of sodium formate (0.5, 2.5 and 5 mM). Figure 3 shows response to gamma radiation of irradiated solutions containing 5 mM NBT with variable concentrations of sodium formate in terms of absorbance at 521 nm against absorbed dose. The results show that the gamma radiation sensitivity increases linearly with increasing absorbed dose up to 30 Gy and it increases from 0.0058 to 0.0115 Gy\(^{-1}\) with increase of sodium formate concentrations from 1 to 5 mM, due to some of the radicals formed from sodium formate which play a role in promoting reduction of NBT [17]. This result is in a good agreement with previous study by [1].

**Effect of additives**

The effect of sodium formate was investigated by preparing three types of solution dosimeters containing 5 mM NBT with variable concentrations of sodium formate (0.5, 2.5 and 5 mM). Figure 3 shows response to gamma radiation of irradiated solutions containing 5 mM NBT with variable concentrations of sodium formate in terms of absorbance at 521 nm against absorbed dose. The results show that the gamma radiation sensitivity increases linearly with increasing absorbed dose up to 30 Gy and it increases from 0.0058 to 0.0115 Gy\(^{-1}\) with increase of sodium formate concentrations from 1 to 5 mM, due to some of the radicals formed from sodium formate which play a role in promoting reduction of NBT [17]. This result is in a good agreement with previous study by [1].

**Effect of pH**

The effect of pH on the radiation induced reduction of NBT dye was investigated by irradiating solution samples containing 5 mM NBT and 5 mM sodium formate with different pH values in the range 5.6–9 at irradiation temperature of 20 ± 1 °C. The pH of the solutions was set with HCl and NaOH, respectively. The optical absorbance of irradiated alkaline solutions has higher values compared to irradiated neutral solutions (see Fig. 4) due to the change of the extinction coefficient of the monof ormazan [11]. Similar findings were observed recently [7,15].

**Effect of irradiation temperature**

The effect of irradiation temperature on the response of NBT solution dosimeters was investigated by irradiating samples containing 5 mM NBT with 5 mM sodium formate (pH = 5.6) to 7.5 kGy and 15 kGy in the temperature range of 5–25 °C. A set of three samples was used for each temperature. The variations in absorbance were normalized with respect to that at an irradiation temperature of 5 °C (see Fig. 5(a and b). The results show that dosimeters depend on irradiation temperature so that, the response of the solutions has to be corrected under actual processing conditions [2]. This result is in agreement with previous work by [8].

Stability of NBT solution dosimeter after irradiation

The stability of NBT solution dosimeters was investigated by measuring the absorbance of NBT solution containing 5 mM NBT (pH $\approx 5.6$), 5 mM NBT with 5 mM sodium formate (pH $\approx 5.6$) and 5 mM NBT with 5 mM sodium formate (pH $\approx 9$). The samples were irradiated to 15 kGy at irradiation temperature of 20°C and kept under normal laboratory conditions in the dark. A set of three solutions was used for each absorbed dose. The stability of irradiated solution changes reasonably (less than $\pm 14\%$; 1σ) up to 2 h, after that the results show no change (less than $\pm 4\%$; 1σ) in the absorbance of the NBT dosimeters up to 7 days (see Fig. 6). This result is in agreement with previous work by [4,12,13].

Effect of X-ray energy

The effect of X-ray energy on the response of NBT solution dosimeters was investigated by using 4 and 18 MV X-ray beam (Varian Medical Systems Inc.). 5 mM NBT with 5 mM sodium formate (pH $\approx 5.6$) solutions dosimeters were irradiated with different doses at 15 cm depth, 100 cm (SSD) set-up and 10 $\times$ 10 cm$^2$ field size. The results show that dosimeters depend on irradiation temperature (see Fig. 7) so that, the response of the solutions has to be corrected under actual processing conditions [2]. This result is in agreement with previous work by [5].

Conclusions

NBT solution dosimeters were prepared with various concentrations of NBT dye from 1 to 5 mM. Systematic evaluation of dosimetric properties for the dosimeters was investigated and found useful for medical dosimetry. The absorbance increases with absorbed dose in the dose range up to 30 Gy. The dose sensitivity increases strongly with increase of concentration of NBT dye. The dose response of NBT dosimeters increases remarkably by addition of various concentrations of sodium formate. It becomes more remarkable with increasing pH value of NBT sodium formate dosimeters. The sensitivity of the solution increased fairly with increase of irradiation temperature, therefore, the response of the solution has to be corrected under actual processing conditions. The stability of solution dosimeters after irradiation was very high up to 30 days.
